Experiment 5: Perceptron vs Multilayer Perceptron (A/B Experiment) with Hyperparameter Tuning

Name: Harishkanna R

Reg No: 3122235001302

Aim and Objective

Aim

The aim of this experiment is to implement and compare the performance of a **Single-Layer Perceptron Learning Algorithm (PLA)** and a **Multilayer Perceptron (MLP)** on a handwritten character recognition dataset.

Objective

- To implement the Perceptron Learning Algorithm (PLA) from scratch using a step activation function and weight update rule.
- To design and train a Multilayer Perceptron (MLP) with hidden layers and non-linear activation functions.
- To preprocess handwritten character images through resizing, flattening, and normalization.
- To perform hyperparameter tuning for the MLP by experimenting with learning rate, batch size, optimizer, and network architecture.
- To evaluate and compare PLA and MLP using accuracy, precision, recall, F1-score, confusion matrix, ROC curves, and convergence plots.
- To analyze the strengths, limitations, and learning behavior of PLA and MLP in an A/B experimental setup.

Justification for Chosen Hyperparameters

Hyperparameter tuning was performed by experimenting with different learning rates, batch sizes, optimizers, and activation functions. The final configuration was selected based on validation accuracy, convergence behavior, and stability during training.

Activation Function (ReLU):
ReLU was chosen for the hidden layers as it provided faster convergence and avoided the vanishing gradient problem compared to Sigmoid and Tanh. It consistently produced higher validation accuracy.

Optimizer (Adam):
The Adam optimizer outperformed SGD and basic gradient descent due to its adaptive learning rate and momentum. Adam showed smoother and faster convergence, especially for the high-dimensional handwritten character dataset.

Learning Rate (0.0005):
A learning rate of 0.0005 achieved stable training without oscillations. Higher learning rates caused unstable convergence, while lower values slowed learning.

Batch Size (64):
A batch size of 64 provided a good balance between convergence speed and generalization. Smaller batch sizes introduced noisy gradients, while larger batches slowed convergence.

Number of Hidden Layers and Neurons:
Two hidden layers with 512 and 256 neurons were selected to provide sufficient model capacity for learning complex non-linear patterns without severe overfitting.

Regularization (Dropout 0.4):
Dropout was used to reduce overfitting by preventing co-adaptation of neurons, improving generalization on unseen data.

Early Stopping:
Early stopping was applied to terminate training when validation loss stopped improving, preventing overfitting and reducing unnecessary computation.

Overall, the chosen hyperparameters resulted in improved convergence, higher accuracy, and better generalization compared to untuned configurations.

A/B Comparison (PLA vs MLP)

An A/B experiment was conducted to compare the performance of the Perceptron Learning Algorithm (PLA) and the Multilayer Perceptron (MLP) on the handwritten character dataset.

Model A: Perceptron Learning Algorithm (PLA)

PLA is a single-layer linear classifier designed for binary classification. It uses a step activation function and updates weights only when misclassification occurs. Due to its linear decision boundary and lack of hidden layers, PLA struggles to learn complex patterns present in handwritten character images.

Model B: Multilayer Perceptron (MLP)

MLP is a feed-forward neural network with multiple hidden layers and non-linear activation functions. It uses backpropagation and gradient-based optimization to learn complex non-linear decision boundaries, making it more suitable for multi-class handwritten character recognition.

Performance Comparison

Aspect	PLA	MLP
Model type	Single-layer	Multi-layer
Classification	Binary	Multi-class
Decision boundary	Linear	Non-linear
Activation function	Step	ReLU (hidden), Softmax (output)
Optimizer	Perceptron update rule	Adam
Accuracy	Low	High
Convergence	Slow / unstable	Fast and smooth
Suitability for images	Poor	Good

Key Observations

- PLA underperforms because handwritten character data is not linearly separable.
- MLP significantly outperforms PLA due to hidden layers and non-linear activation functions.
- Hyperparameter tuning greatly improved MLP convergence speed and accuracy.
- MLP shows better generalization, while PLA fails to scale beyond simple binary tasks.

Conclusion

The A/B comparison clearly demonstrates that MLP is superior to PLA for handwritten character recognition. While PLA is simple and interpretable, it is unsuitable for complex, high-dimensional image data. The tuned MLP effectively learns non-linear patterns and achieves significantly better performance across all evaluation metrics.
